SEMICONDUCTOR DEVICE WITH SELECTIVELY ETCHED SURFACE PASSIVATION

CROSS-REFERENCE TO RELATED APPLICATION

This application is a divisional application of U.S. application Ser. No. 13/533,610, entitled "Semiconductor Device with Selectively Etched Surface Passivation" and filed Jun. 26, 2012, the entire disclosure of which is hereby incorporated by reference.

FIELD OF INVENTION

The present embodiments relate to semiconductor devices.

BACKGROUND

Gallium nitride (GaN) high electron mobility transistor (HEMT) devices have high breakdown voltages and high cutoff frequencies. Such devices are accordingly useful in high power and high efficiency amplifiers and other devices for high frequency communications and other high frequency applications. HEMT devices are also known as heterojunction field effect transistor (HFET) devices in reference to the derivation of a transistor from a heterostructure.

AlGaIn/GaN heterostructures are capable of high speed switching and present high breakdown voltages because of the high breakdown field strength of GaN and the high electron sheet density of the AlGaIn/GaN heterojunction. The high breakdown field strength and high electron sheet density arise from the wide 3.4 eV bandgap of GaN. This bandgap is much wider than the bandgap of other semiconductor materials, such as Si (1 eV bandgap) and GaAs (1.6 eV bandgap). Such GaN heterostructures are accordingly often used in devices calling for highly efficient operation.

GaN HEMT devices have suffered from leakage current and trap-related phenomena, such as current collapse and quiescent current drift. GaN HEMT devices may degrade upon the formation of defects in an AlGaIn barrier layer of the device. The defects provide a leakage path for electrons and effectively lower the Schottky barrier height of the gate. Current collapse is a frequency dispersion phenomenon, and may result from surface and buffer traps.

Field plates have been used to reduce the electric field at the gate edge. The reduction in the electric field in that region may address issues of device degradation and current collapse. GaN caps have also been used to reduce the electric field at the gate edge and improve surface morphology. Silicon nitride films have also been used to decrease the influence of surface traps in the interest of addressing current slump. Despite these efforts, gate leakage remains a problem for AlGaIn/GaN HFET devices with Schottky gates.

BRIEF DESCRIPTION OF THE DRAWINGS

The components and the figures are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention. Moreover, in the figures, like reference numerals designate corresponding parts throughout the different views.

FIG. 1 is a schematic, cross-sectional view of a semiconductor device having selectively etched surface passivation layers in accordance with one embodiment.

FIG. 2 is a schematic, cross-sectional view of a semiconductor device having selectively etched surface passivation

layers, including a patterned surface passivation layer, in accordance with one embodiment.

FIGS. 3-5 are schematic, cross-sectional views of semiconductor devices with a surface passivation layer patterned in accordance with various embodiments.

FIGS. 6-8 are flow diagrams and corresponding schematic, cross-sectional views illustrating an exemplary method of fabricating a semiconductor device involving selective etching of surface passivation layers in accordance with one embodiment.

FIG. 9 is a flow diagram and corresponding schematic, cross-sectional view illustrating an exemplary method of fabricating a semiconductor device involving selective etching of surface passivation layers in accordance with another embodiment.

FIG. 10 is a schematic, cross-sectional view of a semiconductor device having selectively etched surface passivation layers without wet-etching of the surface passivation layer in contact with a semiconductor substrate in accordance with one embodiment.

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENTS

GaN transistor devices with selectively etched surface passivation are described. The selective etching addresses damage that may otherwise occur due to reactive ion etch (RIE), inductively coupled plasma (ICP), or other dry etch procedures used in connection with gate and ohmic contact formation. Gate leakage and inconsistent ohmic contact resistance that may otherwise arise from such damage may thus be reduced. To avoid or address such problems, the disclosed devices include multiple dielectric layers for surface passivation. The multiple dielectric layers may be selectively etched in connection with the gate and/or the ohmic contacts. The surface damage may thus be avoided while still allowing the surface to be passivated in some portions of the device active area by a desired dielectric material, such as silicon nitride (Si_3N_4). For these and other reasons, the disclosed devices may have consistently lower gate leakage and ohmic contact resistances.

The selective etching of the surface passivation may include or involve different etch processing of the dielectric layers to define gate and ohmic contact areas. One dielectric layer may be wet etched, and act as an etch stop for the RIE procedure used to etch another dielectric layer. Etch damage from such RIE procedures may thus be avoided. The absence of etch damage may, in turn, reduce or eliminate gate leakage in Schottky gate HFET devices, such as AlGaIn/GaN HFET devices, in which a dielectric material is deposited on the surface at or near the gate area to address current collapse. The absence of etch damage may also improve the consistency of the ohmic contact resistance.

The selective etching of the dielectric layers may alternatively or additionally include or involve the patterning of the dielectric layer configured for use as an RIE etch stop. The surface passivation in the active area may thus vary as described herein. The patterning may be used to localize the coverage of the etch stop dielectric to selected areas, such as the gate and/or ohmic contact areas and areas proximate thereto to ensure complete coverage of the gate and/or ohmic contact areas. The selective coverage of the etch stop layer may allow one or more portions of the active area to be passivated by Si_3N_4 , the presence of which at the surface may help prevent current collapse. For example, such Si_3N_4 -based passivation may tend to increase the doping of GaN layers because of nitrogen vacancies at the device surface. In con-

3

trast, portions of the active area in contact with or abutting the gate and/or ohmic contact areas may be passivated by the etch stop dielectric so that the etch stop dielectric may be used to protect the gate and ohmic contact areas. Such non-nitride surface passivation in areas near the gate area may be useful to avoid a reaction between Si_3N_4 and one or more Schottky metals, such as nickel, which may otherwise form a conductive NiSi layer capable of causing leakage at the device surface.

Although described below in connection with AlGaIn/GaN HFET devices, the selective etching of the disclosed devices and methods is well suited for use in connection with other devices. For example, the disclosed devices may utilize a wide variety of semiconductor materials, including other types of Group III-nitride semiconductor materials (e.g., InAlN and InGaIn). The disclosed devices are also not limited to Group III-nitride semiconductors, and may instead include other compound semiconductor materials, such as non-nitride-based compound semiconductors (e.g., GaAs) and Group II-Group VI semiconductor materials.

The disclosed devices are also not limited to HFET device configurations. For example, one or more aspects of the disclosed devices and methods may be applied in connection with metal-semiconductor FET (MESFET) devices. The disclosed devices are accordingly not limited to device structures having un-doped semiconductor layers.

The disclosed devices are also not limited to device configurations directed to a particular application or a high voltage context, and may be used in contexts other than RF and power switching.

FIG. 1 is a schematic, cross-sectional view of an exemplary epitaxial GaN transistor device **100** having selectively etched surface passivation in accordance with one embodiment. The transistor device **100** is configured as an HFET or HEMT device. The transistor device **100** includes a semiconductor substrate **102** in which a heterojunction structure is formed on a base substrate **104**. In this example, the base substrate **104** includes SiC. The base substrate **104** may include alternative or additional materials, such as sapphire, Si, GaN, AlN, diamond, poly-SiC, SiC on insulator, silicon on insulator, and other substantially insulating materials.

The semiconductor substrate **102** includes a number of semiconductor layers supported by the base substrate **104** and configured in a heterostructure arrangement. Each of the semiconductor layers may be a Group III-nitride semiconductor epitaxial layer. In other embodiments, one or more of the semiconductor layers is not epitaxially grown. In this example, a buffer/channel layer **106** is grown on the base substrate **104** and configured as a channel and buffer of the transistor device **100**. A bottom or buffer portion **105** of the buffer/channel layer **106** may include undoped (or not intentionally doped) GaN or GaN doped with a p-type dopant such as C or Fe at a level of about 10^{17} to about 10^{19} cm^{-3} to render the buffer portion **105** highly resistive. In embodiments in which the bottom portion **105** is doped, the dopants may be intentionally incorporated during the first 0.1 to 1 μm of epitaxial growth. Undoped subsequent material may then be grown, albeit with the possible incorporation of doping due to "memory effects" present during growth. Alternatively, the buffer portion **105** of the buffer/channel layer **106** may include $\text{Al}_x\text{Ga}_{1-x}\text{N}$ where the Al mole fraction, X, is between 0.03 and 0.06. The thickness of the buffer portion **105** may be between about 0.2 and 5 about microns. The $\text{Al}_x\text{Ga}_{1-x}\text{N}$ may be doped or undoped. An upper or channel portion **107** of the buffer/channel layer **106** may be generally an undoped lower bandgap material relative to a barrier layer **108** (e.g. AlGaIn), such as GaN or $\text{In}_x\text{Ga}_{1-x}\text{N}$ where X is between 0 and 1. The

4

channel portion **107** may be optimized for optimal electron transport and device speed by minimizing the amount of alloy and impurity scattering by avoiding Al-containing alloys or high levels of dopants. The channel portion **107** may have a thickness of about 0.01 to about 1 microns. The AlGaIn barrier layer **108** is disposed on and adjacent to the buffer/channel layer **106**, and a GaN cap layer **110** is disposed on and adjacent to the barrier layer **108**. The AlGaIn barrier layer **108** may have a thickness of about 30 Angstroms to about 400 Angstroms, or thicknesses in the range of about 70 Angstroms to about 250 Angstroms. The cap layer **110** defines a surface **112** of the semiconductor substrate **102**, and may have a thickness of about 10 Angstroms to about 50 Angstroms. One or more of the buffer/channel, barrier, and/or cap layers **106**, **108**, **110** may be doped, un-doped, or unintentionally doped.

The stress-induced polarization resulting from epitaxial growth of the AlGaIn and GaN layers develops a two-dimensional electron gas at the interface between the channel and barrier layers **106** and **108**. The two-dimensional electron gas provides charge carriers for conduction during operation. The GaN cap layer **110** may provide protection for the channel and barrier layers **106** and **108** during subsequent processing steps and may be configured to lower gate leakage.

Other semiconductor materials may be used in the channel, barrier, and/or cap layers **106**, **108**, **110**. In some cases, other Group III-nitride semiconductor materials are used. Such materials may include other binary, ternary, and quaternary compounds. For example, other materials such as InGaIn may be used for the channel layer **106** that have a bandgap less than the bandgap of the barrier layer **108**, as well as a higher electron affinity than the barrier layer **108**. Also, $\text{In}_x\text{Al}_{1-x}\text{N}$, where X may but need not be selected to achieve a lattice match with the channel portion **107** of the buffer/channel layer **106**, may be used for the barrier layer **108**. One or more of the channel, barrier, and/or cap layers **106**, **108**, **110** may be a composite layer.

In other embodiments, additional semiconductor layers may be incorporated into the heterostructure arrangement. For example, buffer, nucleation, and/or transition semiconductor layers may be included in the semiconductor substrate **102**. For instance, an AlN interbarrier layer may be used between the barrier layer **108** and the buffer/channel layer **106**.

One or more isolation regions **114** are formed in the semiconductor substrate **102** to define an active area **116** along the surface **112** of the semiconductor substrate **102**. The isolation regions **114** may be formed via an implantation procedure configured to damage the epitaxial and/or other semiconductor layers of the semiconductor substrate **102**. The configuration and/or fabrication of the isolation regions **114** may vary. For example, the isolation regions **114** may be configured as isolation trenches filled with one or more dielectric materials. In alternative embodiments, the active area **116** of the transistor device **100** is defined via a mesa-etched structure supported by the base substrate **104** and configured to define the heterojunction active area. The semiconductor substrate **102** may thus include such mesa-etched and other semiconductor structures. A number of alignment marks **118** may be formed along the surface **112** outside of the active area **116**.

The transistor device **100** includes a gate **120** supported by the semiconductor substrate **102** to control current flow through the buffer/channel layer **106** in the active area **116**. In this example, the gate **120** is configured as a Schottky gate and is disposed on the cap layer **110**. A variety of materials may be used to form the Schottky contact of the gate **120**, such as one or more of Ni, Pt, NiSi₂, Cu, Pd, Cr, W, etc. The gate **120** may

5

be T-shaped, with a vertically oriented stem as shown. In other embodiments, the gate may be recessed stopping in the AlGaN barrier layer or on an AlN interbarrier layer between the AlGaN barrier layer **108** and the buffer/channel layer **106**.

The gate **120** is disposed between a pair of ohmic contacts **122** supported by the semiconductor substrate **102** in the active area **116**. The ohmic contacts **122** are spaced from one another to define terminals (e.g., source and drain terminals) of the transistor device **100** between which current flows when the channel is formed by a suitable gate control voltage applied to the gate **120**. In this example, the ohmic contacts **122** are disposed on the surface **112** of the semiconductor substrate **102** and are thus deposited on the cap layer **110**. In other embodiments, the ohmic contacts **122** are formed in recesses in the semiconductor substrate **102**, in which case the ohmic contacts may be deposited on, for instance, the barrier layer **108**.

The transistor device **100** includes multiple dielectric layers supported by the semiconductor substrate **102** and configured for surface passivation. A first dielectric layer **124** extends across the active area **116** between the ohmic contacts **122**. The dielectric layer **124** may extend beyond the active area **116** as shown. The dielectric layer **124** includes an opening **126** in which the gate **120** is disposed to establish the Schottky junction at the surface **112** of the semiconductor substrate **102**. The dielectric layer **124** includes further openings **128** in which the ohmic contacts **122** are disposed.

In this example, the dielectric layer **124** includes low pressure chemical vapor deposition (LPCVD) Si_3N_4 . Alternative or additional dielectric materials may be used in the dielectric layer **124**. In some cases, a layer of Si_3N_4 may be deposited via a non-LPCVD procedure. Alternatively, Si_3N_4 may be deposited using plasma-enhanced chemical vapor deposition (PECVD), sputtering, or atomic layer deposition may be used to form the dielectric layer **124**. Other materials such as silicon dioxide (SiO_2), silicon oxide (SiO), silicon oxynitride (SiON) may be used to form the dielectric layer **124** using a variety of techniques, such as LPCVD, PECVD, sputtering, or atomic layer deposition. The dielectric layer **124** may be formed in a multi-layer stack using a variety of materials and techniques, including, for instance, one or more of those referenced above.

A second dielectric layer **130** is disposed between the dielectric layer **124** and the surface **112** of the semiconductor substrate **102**. The first dielectric layer **124** is spaced from the surface **112** by the second dielectric layer **130**. The first dielectric layer **124** may be considered an upper or primary passivation layer, and the second dielectric layer **130** may be considered a lower or intermediary passivation layer. In this embodiment, the second dielectric layer **130** extends across the active area **116** to passivate the entire surface **112** in the active area **116**, including those portions of the surface **112** over the channel layer **106**. The second dielectric layer **130** extends along or covers the surface **112** with the exception of an opening **132** for the gate **120** and openings **134** for the ohmic contacts **122**. The gate **120** is disposed in the openings **126** and **132** to establish a Schottky junction at the surface **112** of the semiconductor substrate **102**, while each ohmic contact **122** is disposed in a respective pair of the openings **128** and **134**.

The second dielectric layer **130** may be configured as an etch stop layer that also acts as a surface passivation layer. In some embodiments, the second dielectric layer **130** includes a wet etchable material having an etch selectivity to a dry etchant of the first dielectric layer **124**. For example, the second dielectric layer **130** may include one or more materials with etch selectivity to fluorine- or fluoride-based and/or

6

other RIE processes used to dry etch Si_3N_4 . Suitable dry etchants include Tetrafluoromethane (CF_4), hexafluoroethane (C_2F_6), and Sulfur hexafluoride (SF_6). Depending on the etch conditions, oxygen and/or argon may be combined with the dry etchants to prevent polymer formation during the dry etch procedure. The second dielectric layer **130** may thus block the dry etchant from reaching the surface **112** of the semiconductor substrate **102** during formation of the openings **126** and **128**. In one example, the second dielectric layer **130** may include aluminum oxide (Al_2O_3) deposited via an atomic layer deposition (ALD), CVD, or other procedures, some of which may involve temperatures of, e.g., about 200 to about 400° C. The Al_2O_3 layer may have a thickness that falls in range from about 3 nm to about 40 nm. In other embodiments, the second dielectric layer **130** may be deposited in-situ after (e.g., immediately after) the semiconductor substrate **102** is complete, but before the semiconductor substrate **102** is exposed to ambient conditions (e.g., outside the deposition chamber). Such deposition may be done using CVD, MBE, or MOCVD. For example, the dielectric layer **130** may include a single amorphous AlN, HfO_2 , or Al_2O_3 layer. The dielectric layer may also include a multi-layer stack in which the Al_2O_3 or AlN layer has a SiN or SiO_2 layer deposited as a top layer for surface protection during processing. In these embodiments, the deposition temperature may be about 200° C. to about 800° C., however, deposition temperatures for the dielectric layer disposed on or in contact with the semiconductor substrate **102** may be less than 600° C. In one example, if the first dielectric layer **124** is selectively etched via a dry etch procedure, e.g., using fluorine- or fluoride-based plasma etchants, the Al_2O_3 in the second dielectric layer **130** stops the etchant at better than 50:1 etch selectivity to Si_3N_4 .

The second dielectric layer **130** may then be etched to form the openings **132** and **134** using a wet etch procedure configured to avoid damage to the surface **112** of the semiconductor substrate **102**. A number of different wet etch processes may be used. In one example, a buffered oxide etch (BOE) procedure is implemented to define the openings **132** and **134**. In Al_2O_3 embodiments, the second dielectric layer **130** may alternatively be removed using a wet etch procedure involving diluted HF.

Additional or alternative dielectric materials may be incorporated into, or used as, the second dielectric layer **130**. The additional or alternative materials may also have an etch selectivity to block an etchant of the first dielectric layer **124**. One such additional or alternative dielectric material is Hafnium oxide (HfO_2). The second dielectric layer **130** may include a mixture of Al_2O_3 and HfO_2 , discrete layers of Al_2O_3 and HfO_2 , or other combination arrangements. The second dielectric layer **130** is not limited to etch resistant materials. For example, the etch stop dielectric layer may include a dielectric stack including a lower or bottom layer of SiO_2 and an upper or top layer of Al_2O_3 and/or HfO_2 . The bottom layer may be configured for compatibility with the semiconductor material (e.g., GaN) at the surface **112**. The top layer may include SiN to protect the wafer during subsequent processing steps. The resistance to etchants of the material(s) in the second dielectric layer **130** may thus vary.

The second dielectric layer **130** may be configured to provide surface passivation in the active area **116**. For example, use of Al_2O_3 in the second dielectric layer **130** provides the passivation function due to the high thermal and chemical stabilities of Al_2O_3 .

In alternative embodiments, one or more additional dielectric layers may be disposed along the surface **112** in the active area **116**. Such layer(s) may be disposed between the first and second dielectric layers **124**, **130**, below the first and second

dielectric layers **124**, **130** adjacent the surface **116**, or above the first and second dielectric layers **124**, **130** in contact with and above the first dielectric layer **124**.

The selective etching of the first and second dielectric layers **124**, **130** allows both the gate **120** and the ohmic contacts **122** to be formed in a manner that avoids damage to the surface **112** of the semiconductor substrate **102**. Damage is avoided by following up the dry etching of the first dielectric layer **124** with a wet etch of the second dielectric layer **130**. The wet etch of the areas for both the ohmic contacts **122** and the gate **120** may thus provide low ohmic contact resistance and low gate leakage, respectively. The wet etch for the gate area **120** may be omitted in embodiments in which the transistor device has a metal-insulator-semiconductor (MIS) gate configuration as shown and described below in connection with the embodiment depicted in FIG. **10**.

The exemplary embodiment shown in FIG. **1** includes a number of other structures to facilitate connections to the gate **120** and the ohmic contacts **122**. For instance, the transistor device **100** may include a patterned metal layer **136** for connections to the ohmic contacts **122**. In this example, the metal layer **136** is also used to define the gate **120**. A second metal layer **138** may then be defined as shown. One or more inter-layer dielectric (ILD) layers **140** may be deposited to isolate the metal layers **136**, **138** and/or for device passivation. In this example, the transistor device **100** also includes a field plate **142** deposited between the ILD layers **140** to shield the gate **120** from high voltages applied to one of the ohmic contacts **122** acting as, for instance, a drain terminal of the transistor device **100**.

The embodiments depicted in FIGS. **2-5** show how the etch stop layer, e.g., the second dielectric layer **130**, may be patterned in further selective etching of the surface passivation layers. With such patterning, the area(s) in which surface passivation is achieved via the etch stop layer may be localized. For example, the etch stop layer may be limited to areas or portions of the active area in the vicinity of the openings for the gate and/or ohmic contacts. Other portions of the active area may thus be covered and passivated by the other dielectric layer (e.g., a Si_3N_4 layer). Such patterning may retain one or more of the advantages of the wet-etched dielectric layer (e.g., Al_2O_3) while allowing for the benefits of other surface passivation layers in areas spaced from gate and/or ohmic contact areas. For example, allowing Si_3N_4 to passivate the surface of the semiconductor substrate may be useful in embodiments having a Group III-nitride semiconductor material such as GaN defining the surface. The presence of LPCVD Si_3N_4 at the surface tends to dope the surface n-type from, e.g., nitrogen vacancies due to the sublimation of GaN, which may occur at temperatures around 675°C . Such extra n-type doping reduces the onset of current collapse in the device. Further details regarding the use of surface passivation of GaN-based transistor devices is set forth in U.S. Patent Publication No. 2007/0241419 ("Transistor and Method with Dual Layer Passivation"). Limiting the lateral extension of the etch stop dielectric beyond the gate area and/or ohmic contact areas may also be useful to the extent that, for instance, a possibility of charge buildup in Al_2O_3 exists. In some cases, the etch stop layer is only present between the gate and drain, as shown and described below in connection with the embodiment of FIG. **4**. With no Al_2O_3 in the source region at all, the configuration may be useful for minimizing source resistance. Using LPCVD Si_3N_4 only in the source region may minimize contact resistance because LPCVD Si_3N_4 passivated material has lower sheet resistance than Al_2O_3 passivated material.

FIG. **2** depicts another exemplary epitaxial GaN transistor device **200** having selectively etched dielectric layers for surface passivation. The transistor device **200** may include a semiconductor substrate **202** having epitaxial Group III-nitride semiconductor layers to define a channel, barrier layer, and cap layer, as described above. A number of other components of the transistor device **200** may be configured in a manner similar to the transistor device **100** of FIG. **1**. For example, the epitaxial semiconductor layers may be grown on a similar base substrate to define a surface **204** of the semiconductor substrate **202**, and isolated to define an active area **206** of the transistor device **200**. The surface **204** is passivated by a dielectric layer **208** (e.g., Si_3N_4) and a patterned etch stop layer **210** (e.g., Al_2O_3). As described above, the dielectric layer **208** may be dry etched (e.g., using Fluorine-based chemistry) and the etch stop layer **210** may be wet etched to define openings for a gate **212** and ohmic contacts **214**.

The patterning of the etch stop layer **210** determines which of the two dielectric layers and, thus, which dielectric material is used to passivate the surface **204** in a particular area. In this example, the etch stop layer **210** is disposed between the dielectric layer **208** and the surface **204** in areas **216**, **218**, and **220**. Each area **216**, **218**, **220** corresponds with a portion of the active area **206** disposed over a channel of the transistor device **200**. The areas **216**, **220** may be adjacent to or abut a respective one of the ohmic contacts **214** (or the openings in which the contacts are disposed), while the area **218** may be adjacent to or abut the gate **212** (or the opening in which the gate **212** is disposed). The patterning of the etch stop layer **210** may thus limit the use of the etch stop to such areas in and around the gate **212** and the ohmic contacts **214**. The remaining portion or portions of the surface **204** may be passivated by the dielectric layer **208**. In this example, the dielectric layer **208** is disposed on the surface **204** in areas **222** and **224**, which correspond with portions of the active area **206** over the channel between the gate **212** and the ohmic contacts **214**. The areas **222** and **224** are accordingly spaced from the gate by the area **218**, and from the ohmic contacts **214** by the area **216** or the area **220**. The etch selectivity of the etch stop layer **210** protects the surface **204** in the openings for the gate **212** and the ohmic contacts from damage that would otherwise arise from the etchant of the dielectric layer **208**.

The areas in which the etch stop layers of the disclosed devices are removed for Si_3N_4 or other surface passivation may vary. For example, the extent to which the etch stop layer extends beyond the area of the opening of the gate or ohmic contact may be customized, and may differ based on the device terminal. As shown in the examples described below, the etch stop layer may extend across the area between one of the ohmic contacts and the gate, while an area between the other ohmic contact and the gate is passivated by the other dielectric layer.

FIG. **3** depicts another exemplary transistor device **300** in which a dielectric layer **302** passivates a surface **304** of a semiconductor substrate **306** in a selected portion of an active area **308**. The portion in this example is an area **310** between a gate **312** and one of a pair of ohmic contacts **314**. To that end, an etch stop layer **316** is patterned to allow the surface **304** to be passivated by the dielectric layer **302** in the area **310**. The etch stop layer **316** may include Al_2O_3 and the dielectric layer **302** may include Si_3N_4 as described above. The etch stop layer **316** may passivate the surface **304** in areas **318** and **320** in contact with or abutting the openings for the gate **312** and one of the ohmic contacts **314**, respectively. The area **310** is spaced from the gate **312** and the ohmic contact **314** by the areas **318**, **320**, respectively. Unlike the embodiment of FIG. **2**, however, the dielectric layer **302** is not disposed on or

adjacent the surface **304** between the gate **312** and the other ohmic contact **314**. In that area, the etch stop layer **316** passivates the surface **304**.

FIGS. **4** and **5** depict further examples of etch stop layer patterning for selective surface passivation in transistor devices **400** and **500**, respectively. The examples show that the patterning of the etch stop layer is not limited to configurations in which the Si_3N_4 layer passivates the surface of the semiconductor substrate only in an area (or areas) spaced from and between the pair of ohmic contacts. The patterning may instead remove the etch stop dielectric from areas (or portions of the active area) abutting one or both of the areas in which the openings for the ohmic contacts are formed.

In FIG. **4**, an etch stop layer **402** is patterned such that the etch stop layer **402** does not abut an ohmic contact **404**, which may be configured as a source terminal of the transistor device **400**. The etch stop layer **402** may be removed entirely from the area in and around the ohmic contact **404**. Alternatively, the etch stop layer **402** may be patterned such that the only remaining portion corresponds with the area to be defined as the opening for the ohmic contact **404**. The etch stop layer **402** may thus protect the surface in the ohmic contact area during dry etch removal of a dielectric layer **406**, such as Si_3N_4 as described above. In either case, the etch stop layer **402** does not extend beyond the ohmic contact **404** after formation of the ohmic contact **404**. Instead, the dielectric layer **406** is thus disposed on the surface in an area **408** abutting the ohmic contact **404**. In contrast, the surface is covered by the etch stop layer **402** in an area **410** between a gate **412** and another ohmic contact **414** (e.g., a drain terminal of the transistor device **400**). Thus, the etch stop layer **402** abuts the ohmic contact **414**. The lateral extent of the etch stop layer **402** in the area **408** may vary. For example, the etch stop layer **402** may either terminate under an overhang **409** or extend past the overhang **409**.

In FIG. **5**, the patterning of an etch stop layer **502** allows a dielectric layer **504** to be disposed on the surface over a wider area **506**. The area **506** abuts an ohmic contact **508** as in the example of FIG. **4**. The ohmic contact **508** may be configured as a drain terminal of the transistor device **500** in this case. Analogous to the description of the transistor device **400** in FIG. **4**, the etch stop layer **502** may be patterned to terminate under or beyond an overhang **509** in an area **512** near a gate **510**. The extent to which the dielectric layer **504** passivates the surface is thus increased in an area **512** near the gate **510** (e.g., under the overhang **509**). The etch stop layer **502** may still cover the portion of the active area in which the opening for another ohmic contact **514** (e.g., a source contact) is eventually formed.

In the example of FIG. **5** (and any other embodiments), alignment marks **516** may be used to align the patterning of the etch stop layer with an ohmic contact opening.

The structure, materials, positioning, and other characteristics of a number of the above-referenced components may vary from the examples shown. For example, the gates of the above-described devices may be fabricated using a T-gate process where the gate metal only touches or abuts the Si_3N_4 (or other upper or top) dielectric layer along a stem of the gate (or other sidewall or vertical face thereof).

FIGS. **6-8** show an exemplary method of device fabrication involving selectively etched surface passivation in accordance with one embodiment. As described above, the device fabrication method may address a number of challenges for HFET or HEMT devices, including gate leakage and/or ohmic contact resistance. The method includes a sequence of acts, only the salient of which are depicted for convenience in illustration. For example, the method may include a number

of acts directed to preparing a base substrate for the assembly method. The ordering of the acts may vary in other embodiments. For example, an isolation implant procedure may be implemented after the annealing of the ohmic contacts.

The method may begin with an act **600** in which a number of epitaxial semiconductor layers are grown on a base substrate (e.g., SiC). The epitaxial semiconductor layers may be grown via one or more techniques, including, for instance, molecular beam epitaxy (MBE), metal-organic chemical vapor deposition (MOCVD), and hydride vapor phase epitaxy (HVPE). The growth of the epitaxial semiconductor layers includes defining a channel of the semiconductor device in a semiconductor substrate. In this example, the channel is defined by growing a GaN or other epitaxial Group III-nitride semiconductor layer on the base substrate. One or more additional epitaxial Group III-nitride semiconductor layers may be grown on the GaN channel layer to define, for instance, a barrier layer and a cap layer. With the growth of these and/or other semiconductor layers, the surface of the semiconductor substrate is defined for an active area of the semiconductor device. One or more of the channel, barrier, and/or cap layers may be deposited via non-epitaxial techniques.

Passivation of the surface begins with the deposition of an etch stop dielectric layer on the surface across the active area in act **602**. The etch stop dielectric layer may include Al_2O_3 . In one example, the surface (e.g., a GaN surface) is covered with a layer of Al_2O_3 having a thickness of about 3 nm to about 40 nm, or a thickness in the range of about 10 nm to about 30 nm. The act **602** may include the deposition of alternative etch stop materials (HfO_2) and/or additional dielectric materials (SiO_2). For example, the etch stop dielectric layer may include a dielectric stack including a lower or bottom layer of SiO_2 or other wet-etchable dielectric film and an upper or top layer of Al_2O_3 and/or HfO_2 . The deposition of the etch stop dielectric layer(s) may be implemented via atomic layer deposition (ALD), PECVD, sputtering, evaporation, LPCVD, electron-cyclotron resonance (ECR) deposition, inductively coupled plasma (ICP), hot-wire CVD (HWCVD), catalytic CVD (CAT-CVD), MOCVD, MBE, HVPE, or other suitable procedure including deposition of these materials in-situ after (e.g., immediately after) epitaxial layer growth as in act **600**, but before exposure to ambient conditions.

In act **604**, the surface passivation continues with the deposition of a passivation layer on the etch stop dielectric layer. The passivation layer may include Si_3N_4 deposited via a LPCVD procedure. The passivation layer extends across the active area over the channel. In some embodiments, the Si_3N_4 is deposited via a technique other than an LPCVD procedure or may include more than one layer deposited by one or more techniques. For example, atomic layer deposition (ALD), PECVD, sputtering, evaporation, LPCVD, electron-cyclotron resonance (ECR) deposition, inductively coupled plasma (ICP), hot-wire CVD (HWCVD), catalytic CVD (CAT-CVD), MOCVD, MBE, HVPE or other suitable procedure including deposition of these materials may be used. In addition, surface passivation act **604** may take place after (e.g., immediately after) act **602** in the same deposition tool, but before exposure to ambient conditions. Materials including the epitaxial semiconductor layers, etch stop layers, and passivation layers deposited during acts **600**, **602**, and **604** may be deposited in-situ in the same or separate chambers of one tool without exposing the semiconductor substrate to ambient conditions.

The LPCVD procedure may be configured to avoid crystallization of the etch stop dielectric layer. For example, the etch stop layer may begin to crystallize at about 800° C. for

Al_2O_3 . Unfortunately, the quality of LPCVD Si_3N_4 may begin to degrade at about that temperature, with significant decreases in quality possible by about 700°C . The LPCVD procedure may thus be implemented at a temperature between about 700°C . and about 800°C . In some embodiments, the LPCVD temperature is about 750°C .

The active area is defined in act 606 via patterning of a photoresist layer and implantation of isolation regions. A number of alignment marks may be deposited outside of the active area before the implantation. The alignment marks may be formed using Si, Titanium-Platinum or other combination or material that provides suitable optical contrast or electron diffraction for e-beam alignment and withstands high-temperature anneals. The alignment marks are schematically shown, such that the positioning of the alignment marks is not necessarily above or otherwise aligned with the isolation region. After the isolation implant and alignment mark deposition, the photoresist may then be removed.

In act 608, ohmic contact areas may be defined by dry etching the LPCVD Si_3N_4 of the passivation layer. In preparation for the dry etch or RIE procedure, a layer of photoresist is applied and patterned as shown. Various plasma etchants may then be used to remove the passivation layer, including, for instance, Fluorine-based etchants, such as SF_6 , CF_4 , etc. In some cases, the etch procedure forms AlF on the surface of the Al_2O_3 layer, thereby stopping the SiN etch. The dry etch procedure may be implemented at a sufficiently low power level (e.g., corresponding with about 30 to about 100 Volts DC bias) to avoid remote damage to the underlying layers (e.g., by passing through the Al_2O_3 etch stop layer).

Once the openings in the LPCVD Si_3N_4 of the passivation layer are formed, the etch stop dielectric layer may be removed in the ohmic contact areas via a wet etch procedure in act 610. Various wet etchants may be used, including, for instance, HF, BOE, and hot HCl. One or more etchants may be used in connection with embodiments having a dielectric stack beneath the LPCVD Si_3N_4 layer. In addition, the ohmic contacts may be recessed using Cl-based chemistry such as Cl_2 , BCl_3 , SiCl_4 or other suitable dry or wet chemistry that etches Group III-V nitrides.

In act 612, the ohmic contacts are formed in the ohmic contact areas. One or more ohmic contact metals and/or other materials are deposited in the opening via evaporation, sputtering, or other procedures. For example, the procedure may include evaporating Silicon to cover the surface of the semiconductor substrate in the contact area before one or more metals may be evaporated (e.g., Titanium and Aluminum), thereby forming a silicide at the interface. Once the metal layers are deposited, a lift-off is implemented to remove the photoresist and metals from outside of the ohmic contact areas. Formation of the ohmic contacts may then include the implementation of an anneal procedure. In one embodiment, the ohmic metal layers are annealed at less than 825°C . In another embodiment, the ohmic metal layers are annealed at less than 800°C . In still other embodiments, the ohmic metal layers are annealed at less than 750°C . The anneal time is optimized to reduce ohmic contact resistance and may last between about 30 and about 90 seconds, although shorter or longer times may be used.

The configuration, materials, and other characteristics of the ohmic contacts may be selected to allow the anneal temperature to stay below the crystallization temperature of the etch stop dielectric layer. Implementing the anneal procedure at an anneal temperature lower than 800°C . may avoid such crystallization and thus the creation of leakage paths. In some cases, the quality of the etch stop dielectric material may begin to degrade at about 800°C . The anneal temperature

may thus be set between about 700°C . and about 800°C ., a range in which low-temperature ohmic contact configurations remain available. In some embodiments, the anneal temperature is about 750°C . to match the temperature of the LPCVD procedure described above. For instance, the formation of the ohmic contact may include creating a recess in the semiconductor substrate before the evaporation of ohmic contact materials. Alternative or additional materials may be used, including the evaporation of silicon into a recess, or the evaporation of Tantalum as a first metal layer instead of Titanium.

FIG. 7 shows a number of acts directed to form a gate of the device. A gate area is defined in act 614 by patterning a photoresist layer and dry etching the Si_3N_4 passivation layer. The RIE procedure may define the stem of the gate. Any one of the plasma etchants referenced above may be used, such that the etch is again stopped by the Al_2O_3 layer. In some embodiments, the etch stop dielectric layer may then be removed in the gate area in act 616 via a wet etch procedure using one of the wet etchants referenced above. In other embodiments, the etch stop dielectric layer is not removed (see, e.g., the embodiment of FIG. 10). In such cases, a separate cleaning procedure, e.g., using dilute HCl at room temperature or other cleaning compound that minimally etches the Al_2O_3 layer, may be used to clean the device surface prior to gate metal deposition. A gate contact is then formed in act 618 in the gate area to form either a Schottky gate or a metal-insulator gate. One or more gate metal layers may be deposited via evaporation, sputtering, or other techniques. In one embodiment, the gate metals include Nickel (Ni) and Gold (Au), with an optional Palladium (Pd) layer deposited on the Ni—Au structure. The gate metal layer(s) may also be deposited on the ohmic contact structures as shown. A metal lift-off procedure is then implemented in act 620 to remove the photoresist layer.

FIG. 8 shows a number of acts directed to completing the fabrication of the device. Multiple cross-sections are depicted for a number of the acts. In act 622, a first device passivation layer is deposited via, for instance, a SiN sputtering procedure. Other procedures may be used, including, for instance, PECVD, ICP, ECR-based deposition techniques. The first device passivation layer is etched in act 624 to define further metal layer areas. A field plate is defined via deposition of a metal layer in act 626. A metal layer is deposited in act 628 and a second device passivation layer is deposited in act 630.

FIG. 9 shows an exemplary method of device fabrication in accordance with an embodiment in which the etch stop dielectric layer is patterned after being deposited on the surface of the semiconductor substrate, as shown in connection with act 900. The etch stop dielectric layer is patterned in the active area to expose one or more portions of the active area in which another dielectric layer, e.g., a Si_3N_4 layer, is used to passivate the surface. The one or more portions of the active area are disposed over the channel of the device, e.g., between the gate and one or both of the ohmic contacts, as described above. A number of procedures may be implemented as part of or before act 900, including the definition of alignment marks.

A passivation layer including, for instance, Si_3N_4 , is then deposited across the active area in act 902. The passivation layer is disposed on the remaining portions of the etch stop dielectric layer in some areas and between such portions on the surface of the semiconductor substrate in the exposed areas. A number of procedures may be implemented as part of act 904, including the definition of the active area using an implant isolation procedure as described above. The ohmic contact areas may be defined and opened via dry and wet etch

13

procedures as described above. In the example shown, both of the ohmic contact openings fall within one of the patterned etch stop layers. Other embodiments may have etch stop patterns that correspond or are aligned with the openings, and/or have one or more openings be defined without any etch stop present. The ohmic contacts are then formed in act 906, and may include one or more procedures configured to prevent the crystallization of the etch stop layer as described above.

The process may then continue with the definition of the gate area in act 908 via photoresist patterning and corresponding dry and wet etch procedures to remove the Si_3N_4 layer and the etch stop layer, respectively. A gate contact may then be formed in the gate area in act 910. In this example, the gate contact is a Schottky contact. In an alternative embodiment, the etch stop layer is not removed before the gate contact is formed. The process may include a number of other acts similar to those described above in connection with the previous embodiment to complete the device fabrication.

FIG. 10 depicts a transistor device 150 having a gate 152 disposed in a metal-insulator gate configuration at a surface 154 of a semiconductor substrate 156. The transistor device 150 may thus be configured as a MISFET device. The transistor device 150 may have a number of components and structures in common with the embodiment shown in FIG. 1. For instance, the transistor device 150 includes first and second dielectric layers 158 and 160 as selectively etched surface passivation layers. The first and second dielectric layers 158 and 160 may be configured as described above. In this embodiment, only the first dielectric layer 158 has an opening 162 in which the gate 152 is disposed. The second dielectric layer 160 is disposed between the gate 152 and the surface 154 to establish the metal-insulator configuration.

The configuration of the MISFET device may vary from the example shown in FIG. 10. For example, the second dielectric layer 160 may be patterned to allow the first dielectric layer 158 to passivate the surface 154 in one or more portions of the active area.

Described above are GaN transistor and other devices having a wet etchable dielectric layer that contacts the GaN or other semiconductor substrate surface and a further dielectric layer on top of the wet etchable dielectric layer. Gate and/or ohmic contact areas are formed by etching both of the dielectric layers. In some embodiments, the wet etchable dielectric layer is patterned to exist in one or more portions of the active area after etching to form the gate and/or ohmic contact areas, such as within the vicinity of the gate and/or ohmic contact areas. The patterning of the wet etchable dielectric layer exposes one or more portions of the active area over the channel such that the further dielectric layer is deposited on the surface in such portions of the active area. Some portions of the active area may thus benefit from passivation by Si_3N_4 . On the other hand, such portions may be limited to un-gated regions to avoid possible gate leakage problems.

In a first aspect, a semiconductor device includes a semiconductor substrate configured to include a channel, a gate supported by the semiconductor substrate to control current flow through the channel, a first dielectric layer supported by the semiconductor substrate and including an opening in which the gate is disposed, and a second dielectric layer disposed between the first dielectric layer and a surface of the semiconductor substrate in a first area over the channel. The second dielectric layer is patterned such that the first dielectric layer is disposed on the surface of the semiconductor substrate in a second area over the channel.

In a second aspect, a heterostructure field effect transistor (HFET) device includes a semiconductor substrate including

14

a base substrate, a Group III nitride semiconductor epitaxial layer supported by the base substrate and configured to include a channel, and at least one isolation region defining an active area along a surface of the semiconductor substrate, first and second ohmic contacts spaced from one another and supported by the semiconductor substrate in the active area, a gate supported by the semiconductor substrate to control current flow through the channel between the first and second ohmic contacts, a first dielectric layer extending between the first and second ohmic contacts and including an opening in which the gate is disposed to establish a Schottky junction at the surface of the semiconductor substrate, and a second dielectric layer disposed between the first dielectric layer and the surface of the semiconductor substrate in a first portion of the active area abutting the gate. The second dielectric layer is patterned such that the first dielectric layer passivates the surface of the semiconductor substrate in a second portion of the active area.

In a third aspect, a method of fabricating a semiconductor device includes defining an active area of the semiconductor device along a surface of a semiconductor substrate, depositing an etch stop dielectric layer on the surface in the active area, patterning the etch stop dielectric layer to expose a portion of the active area over the channel, depositing a passivation layer on the etch stop dielectric layer and on the surface of the semiconductor substrate in the exposed portion of the active area, and defining a gate area by dry etching the passivation layer.

The present invention is defined by the following claims and their equivalents, and nothing in this section should be taken as a limitation on those claims. Further aspects and advantages of the invention are discussed above in conjunction with the preferred embodiments and may be later claimed independently or in combination.

While the invention has been described above by reference to various embodiments, it should be understood that many changes and modifications may be made without departing from the scope of the invention. It is therefore intended that the foregoing detailed description be regarded as illustrative rather than limiting, and that it be understood that it is the following claims, including all equivalents, that are intended to define the spirit and scope of this invention.

The invention claimed is:

1. A method of fabricating a semiconductor device, the method comprising:
 - defining an active area of the semiconductor device along a surface of a semiconductor substrate;
 - depositing an etch stop dielectric layer on the surface in the active area;
 - patterning the etch stop dielectric layer to expose a portion of the active area;
 - depositing a passivation layer on the etch stop dielectric layer and on the surface of the semiconductor substrate in the exposed portion of the active area; and
 - defining a gate area by dry etching the passivation layer.
2. The method of claim 1, wherein:
 - defining the gate area comprises removing the etch stop dielectric layer in the gate area via a wet etch; and
 - the method further comprises forming a Schottky contact in the gate area.
3. The method of claim 1, wherein the semiconductor substrate includes a base substrate and first and second Group III-nitride semiconductor layers epitaxially grown on the base substrate.
4. The method of claim 3, wherein the passivation layer comprises low pressure chemical vapor deposition (LPCVD) silicon nitride.

15

5. The method of claim 1, wherein the etch stop dielectric layer comprises aluminum oxide.

6. The method of claim 1, wherein the etch stop dielectric layer comprises a material having an etch selectivity to block an etchant of the passivation layer from reaching the surface of the semiconductor substrate, the etchant being used in defining the gate area.

7. The method of claim 1, wherein the exposed portion is disposed between the gate area and an area in which the passivation layer is deposited on the etch stop dielectric layer.

8. The method of claim 1, wherein the gate area abuts an area in which the passivation layer is deposited on the etch stop dielectric layer.

9. The method of claim 1, further comprising:
removing the passivation layer via a dry etch in respective areas for first and second ohmic contacts;
removing the etch stop dielectric layer in the respective areas for the first and second ohmic contacts via a wet etch; and
forming the first and second ohmic contacts in the respective areas.

10. The method of claim 9, wherein patterning the etch stop dielectric layer is implemented before removing the passivation layer via the dry etch.

11. The method of claim 9, wherein defining the gate area is implemented after forming the first and second ohmic contacts.

12. A method of fabricating a semiconductor device, the method comprising:

defining an active area of the semiconductor device along a surface of a semiconductor substrate;
depositing an etch stop dielectric layer on the surface in the active area;
patterning the etch stop dielectric layer to expose a portion of the active area;
depositing a passivation layer on the etch stop dielectric layer and on the surface of the semiconductor substrate in the exposed portion of the active area;

16

defining ohmic contact areas via a dry etch to remove the passivation layer and via a wet etch to remove the etch stop dielectric layer;

forming ohmic contacts in the ohmic contact areas; and
defining a gate area by dry etching the passivation layer.

13. The method of claim 12, wherein:

defining the gate area comprises removing the etch stop dielectric layer in the gate area via a further wet etch; and
the method further comprises forming a Schottky contact in the gate area.

14. The method of claim 12, further comprising forming a gate on the etch stop dielectric layer in the gate area.

15. The method of claim 14, wherein the etch stop dielectric layer terminates beyond an overhang of the gate in the gate area.

16. The method of claim 12, wherein:

the semiconductor substrate includes a base substrate and first and second Group III-nitride semiconductor layers epitaxially grown on the base substrate;

the passivation layer comprises low pressure chemical vapor deposition (LPCVD) silicon nitride; and
the etch stop dielectric layer comprises aluminum oxide.

17. The method of claim 12, wherein the second dielectric layer comprises a material having an etch selectivity to block an etchant of the passivation layer from reaching the surface of the semiconductor substrate, the etchant being used in defining the ohmic contact areas and in defining the gate area.

18. The method of claim 12, wherein the exposed portion is disposed between the gate area and an area in which the passivation layer is deposited on the etch stop dielectric layer.

19. The method of claim 12, wherein the gate area abuts an area in which the passivation layer is deposited on the etch stop dielectric layer.

20. The method of claim 12, wherein the etch stop dielectric layer does not abut the ohmic contacts.
